Physics Formulae		
<b>Mechanics</b>	$v = u + at$ $s = ut + \frac{1}{2}at^2$ $v^2 = u^2 + 2as$ $F = ma$ $p = mv$ $E_k = \frac{1}{2}mv^2$ $E_p = mgh$ $E = mc^2$	<b>Electricity &amp; Magnetism</b>
<b>Waves, Sound &amp; Light</b>	$v = f\lambda$ $n = \frac{c}{v}$ $\frac{n_1 \sin \theta_1}{1} = \frac{n_2 \sin \theta_2}{2}$ $\frac{1}{f} = \frac{1}{u} + \frac{1}{v}$ $\frac{1}{f} = \frac{1}{u} + \frac{1}{v}$	<b>Thermodynamics</b>
<b>Modern Physics</b>	$E = hf$ $E = mc^2$ $\lambda = \frac{h}{p}$ $E = mc^2$	<b>Atomic and Nuclear Physics</b>
<b>Optics</b>	$n = \frac{c}{v}$ $\frac{n_1 \sin \theta_1}{1} = \frac{n_2 \sin \theta_2}{2}$ $\frac{1}{f} = \frac{1}{u} + \frac{1}{v}$	<b>Relativity</b>
<b>Particle Physics</b>	$E = mc^2$ $\lambda = \frac{h}{p}$ $E = hf$	<b>Other</b>

Last updated 11 June 2018  
 Designed for students, I created this resource during A Levels to include all A Level Physics formulae not given in the formula sheet. Some of the formulae included in this document are not directly stated in the new specification but were used in the old specification (pre 2015) so may be useful in applied questions. Contains formulae for: Year 1 Particles and Radiation Waves Mechanics Materials Electricity Year 2 Circular Motion Simple Harmonic Motion Thermal Physics Gravitational Fields Electric Fields Capacitance Magnetic Fields Nuclear Physics Optional Topic Medical Physics Creative Commons "Sharealike" Select overall rating (no rating) Your rating is required to reflect your happiness. Write a review Update existing review It's good to leave some feedback. Something went wrong, please try again later. Thanks, very useful Empty reply does not make any sense for the end user Thank you, this is brilliant Empty reply does not make any sense for the end user Report this resource to let us know if it violates our terms and conditions. Our customer service team will review your report and will be in touch. Cheatography Scalar A quantity without direction. Length Distance, Speed, Mass, Temperature, Time, Energy Vector A quantity with both direction and magnitude Displacement, Velocity, Force (inc. Weight), Acceleration, Momentum Equilibrium When all forces acting on an object are balanced and cancel each other out. There is no resultant force Free-body Diagram A diagram of all the forces acting on a body, but not the forces it exerts on other things. The arrows indicate magnitude and direction. Principle of Moments For a body to be in equilibrium, the sum of the clockwise moments equals the sum of the anticlockwise moments. Moment The product of the size of the force and the perpendicular distance between the turning point and the line of action of the force. Couple A pair of forces with equal size which act parallel to each other but in opposite direction. E.g. turning a car's steering wheel. Centre of Mass The single point from which the body's weight acts through. The object will always balance around this point. To calculate for uniform objects:  $E_{mx} = Mx$  SUVAT (Constant Acceleration)  $v = u + at$   $s = \frac{1}{2}(u+v)t$   $v^2 = u^2 + 2as$   $s = ut + \frac{1}{2}at^2$   $s = vt - \frac{1}{2}at^2$  Displacement-Time Graph Displacement (y) against Time (x). Gradient = Velocity Acceleration =  $\frac{\Delta \text{gradient}}{\Delta \text{Time}}$  Velocity-Time Graph Velocity (y) against Time (x). Gradient = Acceleration Area =  $\frac{1}{2} \times \text{base} \times \text{height}$  Acceleration-Time Graph Acceleration (y) against Time (x). Gradient =  $\Delta \text{Acceleration}$  0 Gradient = No acceleration constant velocity. Constant Gradient = constant acceleration Area = Velocity NB: Remember to treat area below the time axis as negative! Newtons 1st Law The velocity of an object will not change unless a resultant force acts on it. Newtons 2nd Law  $F = ma$  The acceleration of an object is  $a$  to the resultant force acting upon it. (for objects with a constant mass) Points to remember: Resultant Force is vector sum of all the forces Unit = N Ensure mass is in kg Acceleration is in the same direction as resultant force. Newtons 3rd Law If object A exerts a force on object B, then object B exerts an equal but opposite force on object A Freefall When there is only gravity acting upon an object. i.e. motion with an acceleration of  $g$  (9.81ms<sup>-2</sup>) The same SUVAT equations apply, however,  $u = 0$  and  $a = g$  (ng)} NB: 'direction' of motion, dictates the sign of  $g$  Projectile Motion An object given an initial velocity, then left to move freely under  $g$ . There is separate horizontal and vertical motion with time being the only common attribute. Both motion follows SUVAT equations but horizontal motion has no acceleration. Friction Force that opposes motion. When in a fluid (liquid or gas) it is drag, drag depends on: Viscosity of the fluid Speed of object Shape of the object For all frictional forces Force is in the opposite direction to motion Can never increase speed or induce motion They convert kinetic energy heat. Lift Upwards force on an object in a fluid Terminal Speed When frictional forces equal the driving force. For a falling object, when drag equals the force due to their mass. Momentum The product of the mass and velocity of an object. Momentum in any collision is conserved (when no external forces are involved) Inelastic Collision Not all of the kinetic energy is conserved. Momentum however is conserved. Elastic Collision Kinetic energy is conserved i.e. no energy is dissipated as heat or other energy forms. Impulse An extension of NZL. Impulse is the product of force and time and is equal to the momentum of that body.  $F \Delta t = \Delta(mv)$  Also equal to the area under a force-time graph. Work Done The energy transferred from one form to another.  $W = Fd$  Work Done = The force causing motion x distance moved Power The rate of work done over time  $P = \frac{\Delta W}{\Delta t}$   $P = Fv$  derived from combining  $P$  and  $W = Fs$  Force-Displacement Graph Area = Work Done Conservation of Energy Energy cannot be created nor destroyed, only converted from one form to another, but the total energy of a closed system will not change. Efficiency useful output/input in terms of energy or power. Density  $\rho = \frac{m}{V}$  A property all materials have and is independent of both shape and size. Limit of Proportionality The point where Hooke's law no longer applies. On a force-extension graph, the limit of proportionality is where the line is no longer straight Hooke's Law  $F = k \Delta L$  The force is proportional to the extension of a stretched wire.  $k$  is the stiffness constant a measure of how hard it is to stretch Elastic Limit The point on a force-extension graph where the line begins to curve. Beyond this point, permanent deformation occurs where the wire will no longer return to its original shape. Force-Extension Graph Straight section Gradient =  $k$  Loading and unloading plot a loop, if a stretch is elastic, the curve starts and finishes in the same position (the origin). If plastic deformation occurs, the unloading line has the same gradient ( $k$ ) but crosses the  $x$  axis at a deformation point Area = Elastic Strain Energy The area between the loading and unloading line (after plastic deformation) is equal to the work done in deforming the material Tensile Stress The ratio of force applied and cross-sectional area.  $\text{stress} = \frac{F}{A}$  Tensile Strain The ratio of extension to original length, it has no units and is just a ratio.  $\text{strain} = \frac{\Delta L}{L}$  Young's Modulus The ratio of tensile stress and tensile strain  $E = \frac{F/L}{\Delta L/A}$  The YM of a material is the constant value up to the limit of proportionality. Stress-Strain Graph Stress (y) against Strain (x). Gradient = Young's Modulus Area = strain energy per unit volume Yield Point The point on a stress-strain graph where the material stretches without any extra load. Brittleness When a material breaks after a certain amount of force is applied. The line simply stops on a stress-strain graph. The same thing applies on a force-extension graph, the line just stops. Kelvin A temperature scale that is in terms of an atoms movements.  $^{\circ}C + 273 = \text{Absolute Zero}$  The lowest theoretical temperature of anything  $^{\circ}K = -273^{\circ}C$  Internal Energy The internal energy of a body is the sum of the randomly distributed kinetic and potential energies of all its particles Closed System A system where no matter or energy is transferred in or out of the system Heat Transfer Heat is always transferred from a hot area/substance to a cold area/substance. Specific Heat Capacity The amount of energy required to heat up 1kg of the material by  $1^{\circ}C$   $Q = mc \Delta T$  Energy Change is equal to the product of the mass, specific heat capacity and the change in temperature. Specific Latent Heat The specific latent heat of fusion (Solid) / vaporisation (gas) is the quantity of thermal energy needed/will be lost to change the state of 1kg of the substance.  $Q = ml$  where  $m$  is the mass and  $l$  the latent heat. When a substance changes state, there is a period where the temperature of the material is constant, as the internal energy rises, this is due to the latent heat. Boyle's Law At a constant temperature,  $pV$  is constant. i.e.  $p_1V_1 = p_2V_2$  On a  $p$ - $V$  plot, the higher the line, the higher the temperature. Charles' Law At a constant pressure:  $V$  is directly proportional to its absolute temperature  $\frac{V_1}{T_1} = \frac{V_2}{T_2}$  Pressure Law At a constant volume:  $p$  is directly proportional to its absolute temperature.  $\frac{p_1}{T_1} = \frac{p_2}{T_2}$  Molecular Mass The sum of the relative atomic masses of all the atoms. Avogadro Constant The number of atoms in exactly 12g of carbon isotope  $12^{12}C$ .  $N_A = 6.02 \times 10^{23} \text{ mol}^{-1}$  Molar Mass The mass of a material containing  $N_A$  molecules Ideal Gas Equations  $pV = nRT$   $n$  = number of moles  $R$  = molar gas constant  $pV = NkT$   $n$  = number of molecules  $k$  = Boltzmann constant A way of remembering which is  $n$  is which. Moles will be small, therefore small  $n$ . Number of molecules will be large so, big  $N$ . Kinetic Theory The pressure exerted by an ideal gas can be derived by considering the gas as individual particles.  $pV = \frac{1}{3} N m \langle c^2 \rangle$   $\langle c^2 \rangle$  is the root mean square speed. Assumptions All molecules in the gas are identical Gas contains a large number of molecules The volume of the molecules is negligible when compared to the volume of the container/gas as a whole. Brownian Motion Random motion of particles suspended in a fluid, helped provide evidence that the movement of the particles was due to the collisions of the fast randomly-moving particles, which supported the model of kinetic theory. Average Kinetic Energy  $\frac{1}{2} m \langle c^2 \rangle = \frac{3}{2} kT$  Proton & Neutrons The 2 Baryons that make up the nucleus of an atom. Comprised of 3 quarks. Protons have a relative charge: +1, neutrons: 0. Both have a relative mass of  $1.67 \times 10^{-27} \text{ kg}$ . Electron A fundamental lepton, with a charge of -1. Cannot be broken down into other subatomic particles. Relative mass of  $1/2000$  ( $9.11 \times 10^{-31} \text{ kg}$ ) Nuclide Notation  $^A_Z X$  The general notation of elements. Proton Number (Z) The number of protons in an atom. Defines the element. For a neutral atom, proton no. also = the electron number Nucleon Number (A) (AKA Mass Number - number of total nucleons (protons + neutrons) Specific Charge The ratio of a particles charge to its mass. Specific meaning per kg. S.C. = Charge (Q) / Mass (kg) Isotope Atoms with the same number of protons but a different number of neutrons. Affects the stability of an atom Strong Nuclear Force A strong force that holds atoms together at small distances, strong enough to overcome the electrostatic repulsion of the protons. Distances Repulsive:  $n \geq 2$  Total Internal Reflection When all light is completely reflected back into a medium at a boundary with another medium instead of being refracted. Occurs when  $\theta_i > \theta_c$  Optical Fibre A very thin flexible tube of glass/plastic fibre in which light signals are carried across long distances and around corners by applying TIR. The fibres are surrounded by a cladding with a high refractive index and a core of a lower refractive index. The light is refracted where the mediums meet and travels along the fibre. Signal Absorption When some of the signals energy is absorbed by the material of the fibre. The final amplitude is reduced. Signal Dispersion When the final pulse is broader than expected, which can cause information loss as it may overlap with another signal. Modal Dispersion Light entering at different angles and taking different paths, resulting in signals arriving in the wrong order Single-mode fibre is used to prevent this - light is only allowed to follow a very narrow path. Material Dispersion Different amounts of dispersion depending on wavelength. Monochromatic light prevents this. Rutherford Scattering An experiment that proved the current model of the atom that it is mostly empty space. Rutherford set up an experiment, with an alpha emitter pointed at gold foil. He observed the deflection of the particles and it showed that atoms have a concentrated mass at the centre and are mostly empty space, which disproved the plum-pudding model which was accepted previously. It showed that: Atoms = mostly empty space Nucleus has a large positive charge, as some of the +ve charged alpha particles are repelled and deflected Nucleus must be tiny due to few particles being deflected by an angle  $> 90^{\circ}$  Mass must be concentrated in the nucleus Distance of Closest Approach  $E_k = E_{elec} = \frac{1}{4\pi\epsilon_0} \frac{q_1 q_2}{r^2}$  where  $r$  is the distance of closest approach Electron Diffraction  $\lambda = \frac{h}{mv}$  where the first minimum occurs at:  $\sin \theta = 1.22 \lambda / 2R$  Nuclear Radius  $R = R_0 A^{1/3}$  Alpha Decay ( $\alpha$ ) Charge(rel): +2 Mass(u): 4 Penetration: low Ionising: high Speed: slow Affected by mag. field: y Stopped by: paper / 10cm air Used for: PET Scanners, in production of metals the levels penetrating through the metal can be used to control the thickness. Gamma Decay ( $\gamma$ ) Charge(rel): 0 Mass(u): 0 Penetration: low Ionising: very weak Speed: c (speed of light) Affected by mag. field: n Stopped by: several cm of lead. Used for: PET Scanners produced through annihilation, cancer treatment. Background Radiation The low level of radiation that always exists. Must be taken into account when measuring radiation. Sources of Background Rad. The Air Radioactive radon gas released from rocks / Ground/Buildings Nearly all rock contains radioactive materials Cosmic Radiation nuclear radiation from particle collisions due to cosmic rays Living things living things are made of carbon, some of which is radioactive carbon-14 Man-Made Radiation from industrial/medical sources Intensity  $I = \frac{P}{4\pi r^2}$  Intensity (Wm<sup>-2</sup>) = constant of proportionality (W) distance from source (m) Radioactive Decay both spontaneous and random. Spontaneous Decay is not affected by external factors Random: It cannot be predicted when the next decay occurs Decay Constant The probability of a specific nucleus decaying per unit time. It is a measure of how quickly an isotope will decay. Activity (Bq) The number of nuclei that will decay each second.  $A = \lambda N$  where  $\lambda$  is the decay constant, and  $N$  is the number of unstable nuclei in the sample. It can also be written as:  $\Delta N / \Delta t = -\lambda N$  ( $\Delta N$  is always a decreasing number hence the neg sign)  $A = \lambda N$  is the activity at  $t = 0$  Number of unstable Nuclei ( $N$ )  $N = N_0 e^{-\lambda t}$  where  $N_0$  is the original number of the unstable nuclei  $n = n_0 A^{\lambda}$  where  $n$  is the number of moles and  $N_A$  is Avogadro's constant Half-Life ( $T_{1/2}$ ) The average time the isotope takes for the number of nuclei to halve.  $T_{1/2} = \frac{\ln 2}{\lambda}$  (Derived from  $N = N_0 e^{-\lambda t}$ ) Uses of Radiation Carbon Dating Using the amount of C-14 left in the organic material. Problems are that the material may have been contaminated, high background count, uncertainty in C-14 in the past and sample size may be too small Medical Diagnosis Tracers that emit radiation to track things in the body Instability Nuclei are unstable when: Too many/not enough neutrons Too many nucleons Too much energy If they nuclei lies on the  $N=Z$  line they are generally stable. If they lie above, they undergo  $\beta^-$  decay, if they lie below, the undergo  $\beta^+$  decay. If they have a  $Z$  number of over  $\sim 82$  (Protons) they undergo  $\alpha$  decay. Mass Defect The mass of a nucleus is less than the mass of its constituents. This energy difference is the mass defect and is lost to energy as  $E = mc^2$ , energy and mass are equivalent. Binding Energy If you were to pull a nucleus apart, this binding energy would be the energy required to do so, equal to the energy released when the nucleus formed. Average Binding Energy Average Binding energy per nucleon = Binding Energy / Nucleon number Nuclear Fission When large unstable nuclei randomly split into smaller more stable nuclei. Energy is released as the smaller nuclei have a higher avg. binding energy per nucleon Nuclear Fusion When 2 smaller nuclei combine to form a larger nuclei. A lot of energy is released because the new heavier nucleus has a higher avg. binding energy (if the 2 original nuclei are light enough). This is the energy that keeps stars burning Nuclear Fission Reactors Control Rods Usually made of carbon, they are lowered and raised to control the rate of fission. The amount of fuel required to produce one fission per fission is the critical mass. Any less (sub-critical) then the reaction will eventually fizzle out. Any more, and the reactor could go into meltdown, which is why control rods are used. Moderator Fuel rods are placed in the moderator, this slows down/absorbs neutrons to control the rate. The choice of moderator needs to slow down the neutrons enough to slow down neutrons enough to keep the rate of fission steady. It slows down neutrons through elastic collisions, a moderator with a similar nucleon-mass to the neutrons. Coolant is sent around the reactor to remove heat produced by the fission. The material is either liquid or gas at room temp. Often it is the same water (heavy-water) as the moderator and can be used to make steam and turn turbines. Shielding Reactors are surrounded by thick concrete, which shields and protects from radiation escaping and anyone working there. Emergency Shut-down All reactors have an emergency shutdown where the control rods are completely lowered into the reactor, thus absorbing all the neutrons produced and slowing the reaction down as quickly as possible. Waste Unused uranium only produces  $\alpha$  so can be easily contained. Spent uranium however emit  $\beta$  &  $\gamma$  radiation. Once removed from the reactor they are cooled and then stored in sealed containers until the activity is at a low enough level. Radian Objects in circular motion travel through angles, mostly measured in radians. Rads to Deg: Angle in deg x  $\frac{\pi}{180}$  Angular Speed The angle an object rotates through per second.  $\omega = \theta/t = v/r = 2\pi/T = 2\pi f$  Frequency The number of revolutions per second.  $f = 1/T$  Time Period The time taken for a complete revolution. Centripetal Acceleration Objects travelling in a circle are accelerating as their velocity is changing constantly. The acceleration is always acting towards the centre of the circle.  $a = v^2/r = \omega^2 r$  Centripetal Force is the resolved force which is always directed towards the centre of the circle.  $F = mv^2/r = m\omega^2 r$  Simple Harmonic Motion An object undergoing SHM is oscillating to and fro, either side of an equilibrium position. It is defined as An oscillation in which the acceleration of an object is directly proportional to its displacement, which is always directed towards the equilibrium position Displacement (x) Displacement varies as a cosine/sine wave with a maximum value of  $A$  (Amplitude)  $x = A \cos(\omega t)$  Velocity (v) Is the gradient of the displacement time graph. Its maximum value is  $\omega A v = \pm \omega \times \text{sqr}(A^2 - x^2)$   $v_{max} = \omega A$  Acceleration (a) Is the gradient of the velocity time graph. Its maximum value is  $\omega^2 A a = \omega^2 \text{Mass-Spring System}$  mass on a spring is a simple harmonic oscillator. When the mass is pulled/pushed from the equilibrium position, there is a force directed back towards the equilibrium position.  $F = -k \Delta L$  where  $k$  is the spring constant and  $\Delta L$  is the displacement. The Time period for a M-S System is given by:  $T = 2\pi \times \text{sqr}(m/k)$  Pendulum A pendulum is an example of a Simple Harmonic Oscillator. The time period for a pendulum is given by:  $T = 2\pi \times \text{sqr}(l/g)$  Free Vibration Free vibrations involve no transfer of energy to/from the surroundings. If a mass-spring system is stretched, it will oscillate at its natural frequency  $f_n$ . Forced Vibration Forced Vibration occurs when there is an external driving force. A system can be forced to vibrate by a periodic external force. This is called the driving frequency,  $f_d$ .  $f_d > f_n$  The oscillator will not be able to keep up and will end up out of control. i.e. completely out of phase. Resonance As  $f_d \rightarrow f_n$ , the system gains more and more energy from the driving force, thus the amplitude rapidly increases. The system is now considered to be resonating. At resonance, the phase difference between the driver and the oscillator is  $90^{\circ}$ . Damping Any oscillating system loses energy to its surroundings damping. System are also deliberately damped to stop them oscillating or minimise resonance. Light Damping Take a long time for oscillation to stop, the amplitude is decreased slowly. Displacement-Time Graph: sharp peak. Heavy Damping The amplitude decreases rapidly, and oscillation takes much less time to stop. Displacement-Time Graph: flat peak. Critical Damping Oscillation is stopped in the shortest amount of time possible. Over Damping Systems with even heavier damping, they take longer to reach equilibrium than a critically damped system. physics alevel aqa keyterms > 21 Pages /media.cheatography.com/storage/thumb/0liec\_a-level-physics-key-terms.750.jpg Your Download Will Begin Automatically in 5 Seconds.
